SECURITY SYSTEM

- A security system is basically made to detect the activity going on near the belonging of the user.
- It makes use of many interconnected components that interact with each other and produce some outputs and accordingly alert the user.
- It alerts the surrounding by various ways like sounding alarm, activating some mechanism to lock the intruder at the place, etc.
- Thus by thinking of the security issue nowadays is very sensible and no one compromises on security.

A security system has been designed by the point of view of not letting anyone else misuses without the administrator's permission.

BASIC COMPONENTS

- Sensors.
- Microcontrollers.
- Motors.
- Actuators.
- Displays.
- Buzzers.
- Cameras

SPECIFICATIONS

- Password verification and validation.
- Alarm or buzzer for user alert.
- Display and keypad to let the user interact with the system.

WORKING PRINCIPLE

- This circuit uses an Arduino UNO R3 board in which the password is already defined along with the code.
- Then the input from the user is taken through keypad and then verified with the stored password.
- After checking the user input and the password, accordingly the further action is taken.
- If password is correct, then the door is opened for 5secs to let the user in and again closed to verify the next user entry again.
- If password is wrong then the buzzer is turned on thus, giving an alert to admin someone is trying to enter the place without the permission.

APPLICATIONS

- In building and office lobbies.
- At homes to allow only home members in and out.
- At kitchens of hotels to allow only kitchen staff to enter the kitchen.
- The areas where isolations along with security is needed.
